
Algorithm 1: The solving and applying algorithm of A_r .

```
1: Given Edge detection results  $D^0 = \{X_1, X_2, \dots, X_i, \dots\}$ ,  $X_i \in \mathbf{R}^{N \times C \times H \times W}$ , where  $D^0$ 
   is an image dataset,  $N$  denotes the batch axis,  $C$  denotes the channel axis,  $H$  and
    $W$  represent the spatial height and width axes, respectively;
2: The binary image  $X_i'$  is generated by using the threshold  $\alpha$  to binarize  $X_i$ , where
    $\alpha$  is a hyperparameter;
3: for  $j \leftarrow 0$  to number of images in  $D^0$  do
4:   Perform two erosion operations on  $X_j'$  using the Conv operation to eliminate
     small areas. Subsequently, apply an expansion operation to fill any remaining
     empty regions. Finally, identify two outlines in the image and record their exact
     locations using two arrays  $[]_1$  and  $[]_2$ .
5:   Define  $S_1$ ,  $S_2$  as the area based on first and second contour circle, respectively.
     To calculate  $A_r \leftarrow S_2/S_1 \times 100\%$  ( $S_1/S_2 = \text{cv2.contourArea}([]_1/[]_2)$ );
6: end
7: The annotation information of  $X_i$  and  $A_r$  calculated by  $X_i'$  were compared, and
   four hyperparameters were defined as the judgment threshold, they are  $a, b, c, d$ ,
   respectively. The adjustment of the hyperparameters and pre-training are started.
8: for  $j \leftarrow 0$  to number of images in  $D^0$  do
9:   if  $A_r$  of  $X_j < a$  then
10:    Write  $X_j$ 's tuyere status as "Pulverized coal lower";
11:   elseif  $A_r$  of  $X_j < b$  then
12:    Write  $X_j$ 's tuyere status as "Normal";
13:   elseif  $A_r$  of  $X_j < c$  then
14:    Write  $X_j$ 's tuyere status as "Leaking";
15:   elseif  $A_r$  of  $X_j < d$  then
16:    Write  $X_j$ 's tuyere status as "Hanging slag";
17:   else
18:    Write  $X_j$ 's tuyere status as "Irrigation slag";
19:   endif
13:end
14: Compare the status value of the subsequently writing with the annotation content,
    repeat steps 8~13, until the accuracy is greater than 90%.
```
